ABSTRACT

Since 1981, the preponderance of population growth has been in the South and West, 1986 population estimates show. California, Texas, and Florida accounted for 53 percent of the national population growth from 1980 to 1986, while Florida passed Illinois to become the fifth most populous state in 1986. Declines in energy-related industries, however, slowed growth in the South and West as growth rates fell sharply the last 3 years in Texas, Louisiana, and Utah. The nation's population continues to age, as the median increased from 30.0 years in 1980 to 31.7 years in 1986. Because of changes in the age structure, households have grown faster than the total population during the 1980s. There are more males than females in Alaska, Hawaii, Nevada, North Dakota, and Wyoming. Males under 18 are the majority in all states, but by age 18 to 24, women predominate in about half the states. The data are illustrated in charts and tables. (SM)

State Population and Household Estimates, With Age, Sex, and Components of Change: 1981 to 1986

INTRODUCTION

This report contains provisional estimates for States of the resident and civilian populations and of households for July 1, 1986, revised annual population and household estimates for July 1, 1981, through 1985, and components of population change for the 1980-86 period. The population and household estimates supersede the estimates for 1981 through 1985 released in Current Population Reports, Series P-25, No. 998.[1]

Also shown are revised annual estimates of the resident population of States, 1981-86, by 10-year age groups and selected broad age groups, and annual estimates by sex. This is the first time that estimates by sex and median age for States have been published in Series P-25.

HIGHLIGHTS

- Florida passed Illinois to become the fifth most populous State in 1986. Florida's 19.8-percent gain since 1980 was the fourth highest after Alaska (32.8 percent), Arizona (22.1 percent), and Nevada (20.3 percent).
- Declines in energy-related industries slowed growth in the South and West. Growth was off sharply the last 3 years in Texas, Louisiana, and Utah. Wyoming and West Virginia have had population losses for the last 3 consecutive years.
- Several Midwestern farming States continued to experience population declines, with Iowa experiencing annual population losses in each of the last 5 years. North Dakota and Nebraska lost population in each of the last 2 years.
- The Nation's population continues to age, as the median increased from 30.0 years in 1980 to 31.7 years in 1986. Florida remains the State with the oldest population with half of its population over 36.0 years of age. Utah has the youngest population with a median age of 25.5.
- The population 65 and over has increased to 29.2 million in 1986 and now represents 12.1 percent of the total population of the United States. Florida's proportion of elderly is the highest of any State at 17.7 percent.
- Persons 25 to 44 constituted 31.5 percent of the U.S. population in 1986. Every State shared in the 13.1 million population gain in this age group between 1980 and 1986.
- Largely because of changes in the age structure, households have grown faster than the total population during the 1980's.
- While the Northeast and Midwest accounted for only 9 percent of national population growth in the 1980-86 period, they accounted for 26 percent of the national increase in households.
- California, Texas, and Florida accounted for 53 percent of national population growth from 1980 to 1986, but for only 37 percent of household growth.
- The four States that lost population between 1980 and 1986—Ohio, Michigan, Iowa, and West Virginia—all had increases in households during the same period.

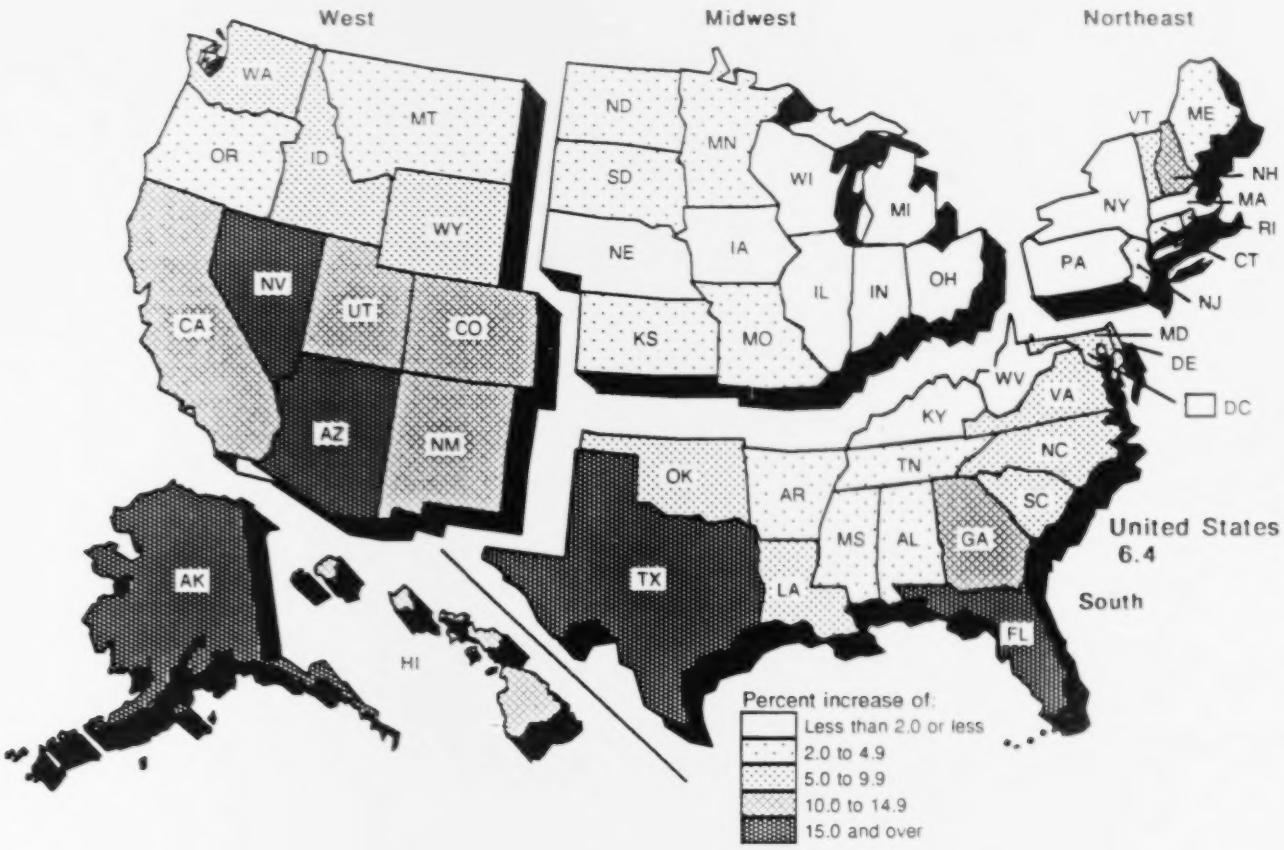
POPULATION TRENDS

The geographic trends in population movement observed in the first half of the 1980's have continued into the second half of this decade. The preponderance of growth has been in the South and West, with the States in these two regions absorbing 90.9 percent of the Nation's 14.5 million gain between April 1, 1980, and July 1, 1986. Slightly over half of their combined population increase of 13.2 million was attributable to net inmigration, both from other States and from outside the United States. Table A shows California as the State with the largest amount of population increase in the 1980's (3.3 million), while table B shows Alaska has experienced the highest rate of increase at 32.8 percent. Alaska's growth rate peaked in 1982-83, and has declined each year since then.

Except for New Hampshire, every State in the North grew less rapidly than the national rate of 6.2 percent. However, 10 States in the South and 3 States in the West, as well as the District of Columbia

[1]Estimates of the resident population of States for 1985 and 1986 were previously released in December 1986 in Census Bureau Press Release CB87-02, as were estimates of households for States for 1985 and 1986 in April 1987 in Census Bureau Press Release CB87-65.

Figure 2. Percent Change in Population, by State: 1980-86



grew more slowly than the Nation as a whole. Seven Southern and Western States, and the District of Columbia experienced net outmigration between 1980 and 1986, although only the District of Columbia and West Virginia recorded population losses during the period.

The 3-year declines in the energy industry have been mirrored by declines in population growth in several energy-producing States, concentrated in the South and the West. Since 1983, growth rates in Texas, Louisana, and Utah have fallen off sharply, while Wyoming and West Virginia have experienced 3 years of population losses. Montana lost population last year, and Oklahoma has lost in both of the last 2 years.

The Northeast grew by 1.8 percent between 1980 and 1986, with every State sharing in the gain. New Hampshire showed the highest growth rate in this

Table A. States Ranked by Largest Numerical Increase in Population: 1980-86 and 1970-80

(Numbers in thousands)

State	Increase	Net migration	Rank	State	Increase	Net migration
1980-86				1970-80		
California	3,313	+1,778	1	California	3,697	+1,573

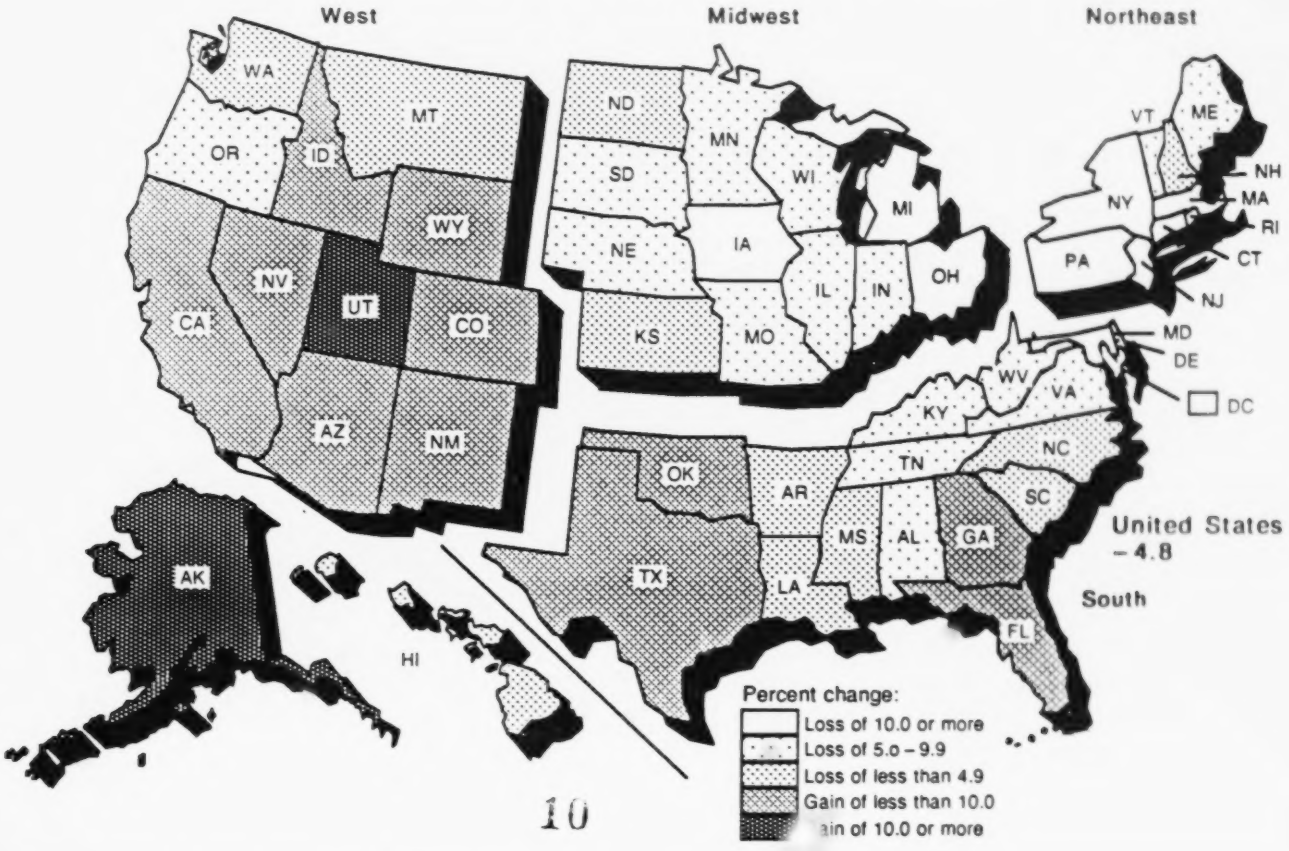
Georgia	11.7	+6.5	10	Texas	27.1	+13.2

region with 11.5 percent, and last year,Pennsylvania rebounded with a slight increase (0.2 percent) after 2 years of small losses in population.

The Midwest has maintained slow growth since 1983, though its total gain for the decade has yet to reach half a million. Of the region's 12 States, three (Iowa, Michigan, and Ohio) had smaller populations in 1986 than in 1980.

Recovery in the Midwest has been slowed in States where agriculture plays an especially important role in the economy. Iowa has experienced an annual decrease in population since 1981, with a loss last year of nearly 31,000 persons or -1.1 percent. Iowa had the highest rate of net outmigration (-5.7 percent) of any State so far this decade. South Dakota also lost population last year, and North Dakota and Nebraska lost in each of the last 2 years. By contrast, Michigan, Ohio, and Indiana are continuing their upward turnaround after population losses in the early 1980's.

Figure 3. Percent Change in the Population 5 to 17 Years, by State: 1980-86



TRENDS IN AGE DISTRIBUTION

Differential patterns of fertility and of movement into and out of States have resulted in changes in State age distributions. Since the majority of population growth in the 1980's has occurred in the South and West, the population change in age groups has generally been numerically positive in the States in these two regions. Where age groups increased nationally, these States had a larger percentage increase; where age groups have declined in population, these States grew or declined less than the United States did.

The progeny of the Baby Boom have swelled the ranks of the under-5 age group to 18.1 million, its highest level since July 1967. Between 1980 and 1986, the age group under 5 grew by nearly 1.8 million, or 10.9 percent. Alaska registered the highest 1980-86 percent increase at 55.3 percent, with Florida next at 37.1 percent (table 7). West Virginia marked the largest rate of decline in this age group, (-16.1 percent) for the decade. Table 8 shows Alaska and Utah tied for the highest proportion of their population under 5 years of age (11.3 percent).

Nationally, the population in the 5 to 17 age group has declined by 4.8 percent so far this decade (figure 3). Only a quarter of the States had population increases in this age group, with Utah the highest at 23.1 percent followed by Alaska at 20.7 percent. The decline in the school-age population will soon reverse as the larger birth cohorts from the early 1980's enter this age group. Since 1984, there has already been a turnaround, with the population 5 to 17 growing by 0.4 percent.

The 1980's have seen the Nation's young adult population (18 to 24) shrink by 2.3 million or 7.6 percent. The proportion of 18-to-24-year-olds to the all-ages population dropped from 13.3 percent in 1980 to 11.5 percent in 1986, and this age group will continue to shrink in the near future. Only New Hampshire in the North, and four Southern and Western States (Georgia, Florida, Arizona, and Arkansas) showed growth in this age group.

The 25-44 age group now constitutes 31.5 percent of our Nation's population. The 20.9-percent increase in this age group makes it the fastest growing age segment of the 1980's, with every State sharing in the growth of this group since 1980.

Growth in the age group 45 to 64 remains slow at 1.2 percent. Nationally, the proportion of 45-to-64-year-olds dropped nearly 1 percentage point, from 19.6 percent in 1980 to 18.7 percent in 1986. Just over half the States experienced losses in their middle-aged population between 1980 and 1986. Alaska was among the States that did grow, increasing by 44.7 percent, followed by Florida at 16.7 percent.

From 1980 to 1986, the older population expanded by over 3.6 million persons or 14.2 percent. Every State registered increases in the age group 65 and over, with 11 States gaining over 20 percent. California added the largest number of persons in this age group at (433,000). The elderly constitute 12.1 percent of America's total population; in Florida, they constitute 17.7 percent of the population—the largest proportion in any State.

The aging of America is evidenced by the 1.7 years increase in the median age, from 30.0 years in 1980 to 31.7 years in 1986. Nearly half the States increased their median age by 2 years or more between 1980 and 1986; Hawaii marked the highest increase with 2.6 years. The aging trend is expected to continue as the leading edge of the Baby Boom heads toward middle age.

Florida is also the State with the highest median age at 36.0 years (figure 1 and table C). The next highest is New Jersey (34.0 years), and 7 of the 10 highest median ages in 1986 were in Northeastern States. Utah's high birth rate made it the State with the lowest 1986 median age (25.5 years).

Table C. States Ranked by Median Age: July 1, 1986

Rank	State	Median age	Rank	State	Median age	Rank	State	Median age
1	Florida	36.0	19	Washington	31.9	37	Alabama	31.0
2	New Jersey	34.1	20	Nevada	31.9	38	South Dakota	31.0

17	Virginia	49.1	35	West Virginia	48.4		United States	48.7
18	Minnesota	49.1	36	Georgia	48.4			

Nationally, the 1986 female median age (32.9 years) is 2.3 years higher than the male median age (30.6). In Florida, the difference between the medians is the highest at 3.4 years, and in Nevada, it is the smallest with only 0.4 years difference. Alaska is the only State where the 1986 male median age (28.8 years) is higher than the median age for females (27.9 years). Table D shows that Alaska, Hawaii, Nevada, North Dakota, and Wyoming are the only States with a preponderance of males.

HOUSEHOLD TRENDS

The distribution of households among the States is similar to the distribution of population. This reflects the fact that a relatively small proportion of the population of each State does not live in households (i.e., lives in group quarters), and that the average number of persons per household is similar to the national figure in most States.[2]

On July 1, 1986, the estimated number of households in the United States was 88.8 million. The estimates ranged from 9.8 million in California to 179,000 in Alaska (table 9). The 10 States with the highest estimated numbers of households in 1986 are shown in table E. With the exception of Florida and Pennsylvania, the ranking by number of households for these 10 States is identical to their ranking in total population. Florida ranked fifth in population but fourth in households ahead of Pennsylvania.

From 1980 to 1986, the estimated national increase in households was 10.5 percent, compared with 6.4 percent in resident population (figure 4). The more rapid growth in households than in population results from changes in age structure. From 1980 to 1986, the population 18 years and over, which includes virtually all householders, increased by 9.2 percent.[3] The number of persons under age 18 declined by 0.8 percent and dropped from 28.1 percent to 26.2 percent of the total population.[4] Data on household size from the Current Population Survey for March 1980 and 1986 reflect the change in age structure. The decline in the average number of persons per household (2.76 to 2.67) was primarily due to the drop among persons under age 18 (0.79 to 0.71).[5]

Households increased faster than population in all States except California where the percentage increases were the same. The estimated percent increase in households for States was up to 7 percentage points higher than the percent increase in population in the 1980-86 period (tables 1 and 9). (See Evaluation of Household Estimates.) In general, the differences were largest in those States with the largest proportionate increases in the population 18 years and over during the 1980-86 period (table 8). (See Methodology regarding the use of estimates of the population 18 years and over to estimate households.)

[2]In 1980, 2.5 percent of the U.S. population lived in group quarters, with the figure for States ranging from 1.5 percent in Nevada to 4.1 percent in Vermont, North Dakota, and Hawaii. The average number of persons per household was 2.75 and ranged from 2.55 in Florida to 3.20 in Utah. Except for Utah and Hawaii (3.15), the range for States was 2.55 to 2.97. In the District of Columbia, 5.0 percent of the population lived in group quarters, and the average number of persons per household was 2.40. See 1980 Census of Population, Volume 1, Chapter B., Part 1, table 61 (1983).

[3]If the age-specific householder rates (the proportions of the household population by age who are householders) in March 1986 had been the same as in March 1980, there would have been an 11.0-percent increase in households during this period. The age structure *within* the population 18 years and over became more favorable to household growth during this period. The proportion declined in the 18-24 age group (in which householder rates are low) and increased in the 65-and-over age group (in which householder rates are high).

[4]Table 8 and Current Population Reports, Series P-25, No. 1000, *Estimates of the Population of the United States, by Age, Sex, and Race: 1980 to 1986*, tables 2 and 4 (February 1987).

[5]Current Population Reports, Series P-20, No. 412, *Households, Families, Marital Status, and Living Arrangements: March 1986 (Advance Report)*, table 2 (November 1986).

Table E. States Ranked by Largest Number and Increase in Households: 1980-86

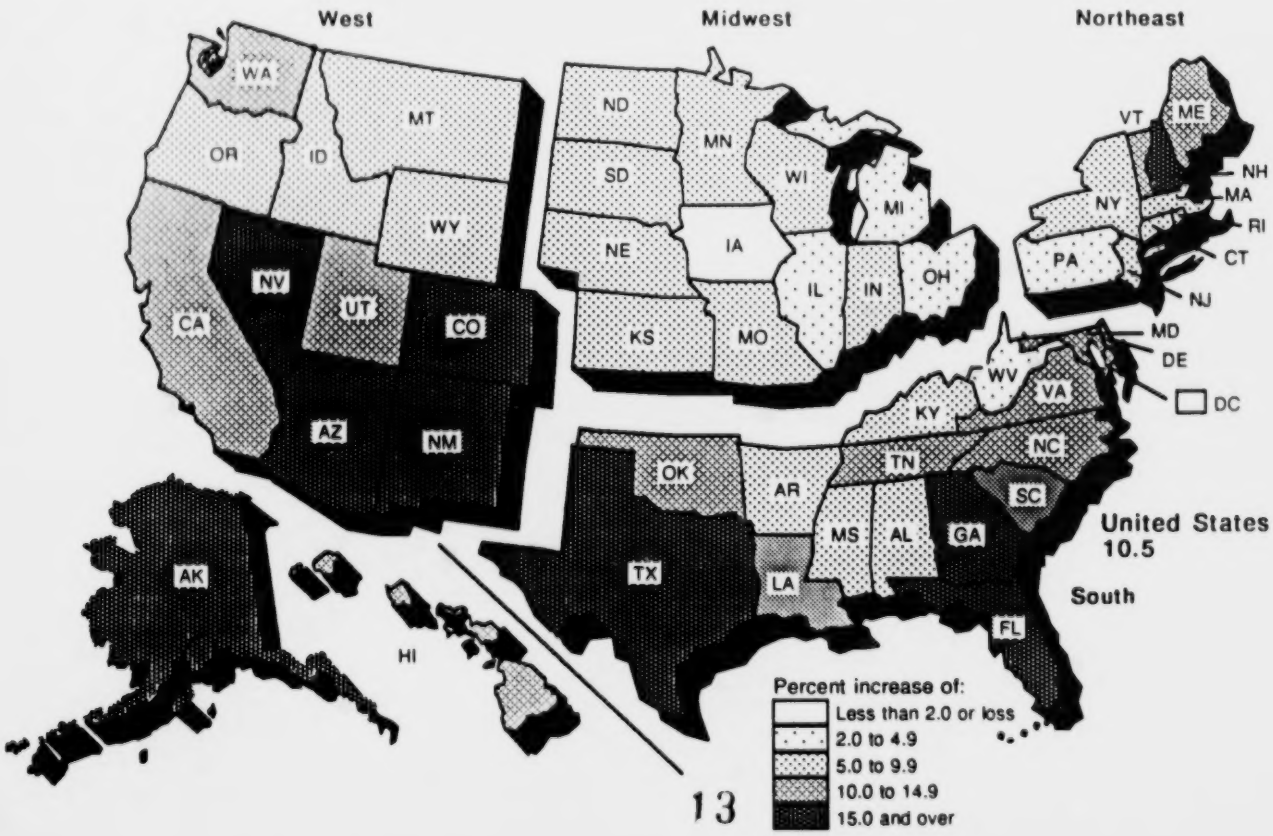
(Numbers in thousands)

Rank	State	Number of households, 1986	State	Numerical increase in households, 1980-86	State	Percent increase in households, 1980-86
1	California	9,842	California	1,212	Alaska	36.2
2	New York	6,672	Texas	987	Arizona	26.3
3	Texas	5,916	Florida	891	Nevada	25.1
4	Florida	4,636	New York	331	Florida	23.8
5	Pennsylvania	4,411	Georgia	328	Texas	20.0
6	Illinois	4,237	North Carolina	296	New Mexico	18.4
7	Ohio	3,998	Virginia	259	Georgia	17.5
8	Michigan	3,315	Arizona	252	New Hampshire	17.1
9	New Jersey	2,776	New Jersey	228	Colorado	16.8
10	North Carolina	2,340	Illinois	191	Utah	14.6

While the North (Northeast and Midwest Regions) accounted for only 9 percent of national population growth in the 1980-86 period, it accounted for 26 percent of household growth. The population in the North increased by 1.3 million (1.2 percent) from 1980 to 1986 as households in the North increased by 2.2 million (5.7 percent). In the South and West, the population grew by 13.2 million (11.1 percent), while households rose by 6.2 million (14.8 percent).

The three States with the largest numerical increase in population in the 1980-86 period—California, Texas, and Florida—also led in household growth; however, they accounted for less of the national growth in households than in population: 37 percent versus 53 percent (tables 1 and 9). New York, New Jersey, and Illinois, which had low population growth rates, were among the 10 States with the largest numerical increases in households from 1980 to 1986 (table E). During this period, four States (Ohio, Michigan, Iowa, and West Virginia) lost population; however, they all had estimated increases in households (table 9).

Figure 4. Percent Change in Households, by State: 1980-86



Alaska, which had the highest rate of population growth in the 1980-86 period, also had the highest rate of household growth (tables B and E). Eight other States ranked in the top 10 in rates of population and household growth: Arizona, Nevada, Florida, Texas, Utah, New Mexico, Colorado, and Georgia.

METHODOLOGY

Total Population Estimates

The population estimates for the 1980's contained in this report are developed by averaging the results of two methods, both of which use current data to estimate population change since April 1, 1980.[6]

The Census Bureau's Composite method estimates two age segments—the population under 15 years of age and the household population 15 to 64 years of age. The under-15 age group estimate is obtained by using vital statistics and school enrollment figures to estimate migration in a component procedure. For the household population 15 to 64 years old, this method employs a ratio-correlation technique in which a multiple regression estimating equation is applied to the changes in three independent variables (Federal income tax returns, school enrollment, and housing units) to estimate changes in the population.

The second method (the Administrative Records method) is a component procedure that estimates the household population under 65 years of age. In this method, net internal migration is estimated using individual income tax returns; net immigration from abroad is developed from immigration reports, and reported vital statistics are used to account for natural increase.[7]

The population 65 years and over and the group quarters population under 65 years old are added to the household population under 65 from each of the methods, resulting in an estimate of the total resident population. The two methods are then averaged to produce a final State estimate.

Estimates of the group quarters population are obtained by adding to the 1980 census count of nonbarracks group quarters population the latest survey data on military barracks population. The population aged 65 and over is obtained by adding the estimated change in the number of people enrolled under Medicare between April 1, 1980, and the estimate date to the 1980 census population aged 65 and over.[8] Civilian population estimates are created by subtracting Armed Forces from the resident State population estimate. The Armed Forces data are obtained directly from reports of the Departments of Defense and Transportation (Coast Guard) showing the number of military personnel assigned to each installation, adjusted where necessary to reflect place of residence.

A more detailed description of the methodology for total State population estimates and an indication of their accuracy may be found in Current Population Reports, Series P-25, No. 957.

Age-Sex Estimates

The methodology used to produce the age and sex estimates in this report is an updated and expanded version of the component procedure (Component Method II) used by the Census Bureau since the 1950's. The method has been modified to estimate state population by sex and by single year of age, but the single years of age have been aggregated to broad age groups for publication purposes. The median ages in this report are calculated from the single year of age detail.

The component procedure applies only to the population under 65 years of age. For each individual age, the estimating procedure follows the standard demographic formula of $P_1 = P_0 + B - D + M$: where P_1 is the population on the estimate date; P_0 is the population on the census date; B and D are the births and deaths occurring during the estimate period (between the census and the estimate date), and M is the net migration (including net immigration from abroad) occurring during the estimate period.[9] The population estimates for ages 65 and over are not based on a component procedure, but are derived using changes in Medicare enrollment. A more detailed explanation follows later in this section.

The components used in estimating single years of age (ages 0 to 64) for the civilian population are summarized below:

1. The resident cohort population by single year of age is developed by carrying forward the April 1, 1980, census count (for each age) to the July 1 estimate date;

2. Births entering the cohorts for the period between April 1, 1980, and the estimate date are added. (This affects only the population under age 6.)

[6]Estimates for Utah are based only on the Administrative Records estimate. The large numbers of births in the State bias the school enrollment statistics as used in the Ratio-Correlation part of the Composite method.

[7]The net immigration component includes an allowance for both foreign- born emigration and undocumented immigration as well as legal immigration. For a more detailed explanation, see Current Population Reports, Series P-25, No. 998.

[8]See the age-sex estimates methodology for more detail on the 65-and-over population.

[9]Births are included only for ages under 6 years old in 1986.

3. An estimate of the Armed Forces cohort population (ages 17 to 64 on the estimate date) is subtracted from the resident cohort population to create the civilian cohort population;

4. An estimate of civilian cohort deaths is subtracted;

5. An estimate of net civilian migration for 1980 to the estimate date is added;

6. An estimate of the loss of civilian population entering the Armed Forces population during the period is accounted for.

The above components are not developed by sex. Instead a State-specific sex ratio (by age) is applied to the civilian population to produce civilian sex detail for single years of age (ages 0 to 64) on the estimate date.[10] As a final step, each age-sex cell is adjusted to sum to an independent national population estimate for that age-sex cell.[11]

In addition, the age-sex cells within a State are adjusted to equal the civilian population of the State published in table 2 of this report. Estimates of Armed Forces by age and sex are added to the civilian population to produce resident population estimates.

Vital statistics. Final births by place of residence for calendar years 1980 through 1984 are obtained from individual State vital statistics offices along with provisional estimates of births for calendar year 1985. Births for the first 6 months of 1986 for each State are estimated by using one-half of the 1985 State calendar year totals adjusted pro rata to the reported national total for January-June 1986.

Calendar year resident deaths for States from 1980 to 1984 for ages under 1, 1-4, and 5-year age groups thereafter, are obtained from the National Center for Health Statistics. Deaths for 1985 and 1986 are estimated by duplicating 1984 data. National proportions are used to convert the State 5-year deaths to single year deaths. Separation factors are used in apportioning deaths under 1 year of age.[12] Deaths by single year of age are used to develop deaths to the school-age cohort and single year of age cohorts. National Armed Forces deaths are obtained from the Departments of Defense and Transportation. Since deaths to the military are only available at the National level, both the level of State military deaths and the age-sex distribution are assumed to follow the national trends.

Migration. The procedures for deriving the net civilian migration component by single years of age may be outlined in three major steps.

In the first step, it is assumed an accurate measurement of school-age migration can be deduced from school enrollment data. The first step yields two products—a State school-age net migration amount and a State school-age net migration rate for each estimate period (i.e., April 1, 1980 to estimate date).

The school enrollment data are for grades 1 through 8 (plus elementary special and ungraded enrollment) for the fall prior to the estimate date and for fall 1979.

The ratio of the school-age population (age 6.50 to 14.49) to enrollment in 1980 is applied to the school enrollment collected for the estimate year. The resulting estimates of school-age population are then adjusted pro rata to an independent national school-age estimate. The estimate of the period school-age migration for each State is derived from the difference between the school-age population developed from the school enrollment data and the school-age population expected by surviving the school-age cohort from the 1980 census. Deaths by single years of age are used in surviving the cohort. A school-age migration rate for each State is developed by dividing the amount of period migration by the school-age cohort population on the estimate date minus one half the school-age cohort deaths.

The second major step is to formulate the period net migration component for single years of age between ages 0 and 16. This is done by disaggregating the cumulative school-age migration from step 1 into migration estimates by single years of age (ages 6 to 13) for annual intervals.[13] Each single age in the school-age range is assumed to share equally in the amount of school-age migration, so that each age is accorded one-eighth of the *cumulative* amount of school-age migration. To derive period migration for the entire age group of 0-16 years, this assumption is applied to each age under 17 years (age zero is an exception, see below), but is modified on the basis of age and length of exposure to migration.

Formulas to convert school-age migration to annual migration for single years of age (ages 0-16) are established for a decade of estimate periods (e.g., 1981 to 1990). For the first 6 years of the estimate periods (e.g., 1981 to 1986) the conversion of cumulative school-age migration to annual migration for a single age is rather straightforward. Since every age in the school-age population (6-13) has the same amount of exposure to migration in this period, each single age from 1 through 16 years receives one-eighth of the annual school-age migration for each year. The following equations represent the estimation of annual migration for each age in

[10]Derivation of the sex ratios is described later in this section.

[11]National population estimates for the 1980's may be found in Current Population Reports, Series P-25, No. 1000.

[12]The probability of dying during the first year of life is inversely related to age. That is, death is more likely to occur just after birth, than at 11 months of age. To reflect this fact, factors (called separation factors) are applied to the under-1 deaths, when calculating cohort deaths.

[13]To simplify the estimation equations and their derivation, the eight school-age years are assumed to be ages 6.0 to 13.99 rather than 6.5 to 14.49. Also, the estimate period is assumed to be in whole numbers of years.

the range 1 to 16 years based on cumulative school-age migration for the period:

Let Zy = *annual* amount of migration for a single age (age 1 through 16 years) in estimate year y

M_p = *cumulative* amount of school-age migration for estimate period p, i.e., 1980 to 1980 + p

Then, for the first 6 years of the estimation period:

Estimate year 1: $Z_1 = M_1/8$
Estimate year 2: $Z_2 = (M_2-M_1)/8$
Estimate year 3: $Z_3 = (M_3-M_2)/8$
Estimate year 4: $Z_4 = (M_4-M_3)/8$
Estimate year 5: $Z_5 = (M_5-M_4)/8$
Estimate year 6: $Z_6 = (M_6-M_5)/8$

The group under 1 year of age (age 0) in any year has only one-half year of exposure to migration, on average, so that it is assumed to have only 1/2 of 1/8 (or 1/16) of school-age migration in the year. For example, the migration component for the 1981 estimate for age 0 is calculated using the formula $(1/2)\cdot(1/8)\cdot M_1$ or $(1/16)\cdot M_1$, whereas $(1/8)\cdot M_1$ is used for ages 1 through 16 in 1981.

The conversion of cumulative school-age migration for years 7 through 10 of the estimating period (e.g., 1987 to 1990), to an annual amount of migration for each age is complicated by the fact that some of the single year of age cohorts in the 0 to 16 age range were not born at the beginning of the period (e.g., four year olds in 1985). Thus, each individual age group, and the entire school-age population as well, has varying periods of exposure to migration depending on the estimate year and the age. The estimating equations for these years are as follows:

Estimate year 7: $Z_7 = ((M_7-M_6)/8) + (1/128\cdot M_1)$
Estimate year 8: $Z_8 = ((M_8-M_7)/8) + (1/128\cdot M_2) + (1/128\cdot M_1)$
Estimate year 9: $Z_9 = ((M_9-M_8)/8) + (1/128\cdot M_3) + (1/128\cdot M_2)$
Estimate year 10: $Z_{10} = ((M_{10}-M_9)/8) + (1/128\cdot M_4) + (1/128\cdot M_3)$

Note that the initial term follows the pattern of the first six periods; and the other term(s) are relatively small.

The annual amounts of migration estimated for years 7 through 10 (Z_7 through Z_{10}) apply to each age (ages 1 to 16) in the estimate year, in the same manner as with years 1 through 6. The estimated migration for age 0 in years 7 through 10 is again assumed to be only half of that calculated for any other single year of age.

The third and final step is to develop the period net migration component for single years of age between ages 17 and 64. The school-age migration rates from step 1 are used in this calculation. The principal assumption is that the 1975-80 relationships (from the census) between a State's school-age migration rate and its single year of age rates in ages 17-64 remains constant between 1980 and 1990. This relationship is expressed in terms of migration differentials.

The migration differentials are based on 1975-80 State migration patterns from the 1980 census. State specific inmigration and outmigration rates by single year of age are developed for the civilian population for the 1975-80 period. The rates are smoothed, but the original rates for 18- and 19-year-olds are held constant, to maintain the sharp increase in migration that is expected at those ages.[14] The smoothed 5-year inmigration and outmigration rates are then converted to annual rates. Annual net migration rates are derived by subtracting the outmigration rates from the inmigration rates.

The smoothed annual net migration rates for 1975-80 are used to project a 10-year period of net migration (1980-90) by single year of age. The cumulative 10-year projected migration for eight single years (ages 6 to 13) making up the school-age population are accumulated to form school-age migration. Both the school-age migration and each single year of migration are converted to rates. The difference between the migration rate for each single year of age (ages 17-64) and the school-age migration rate is known as the migration differential. Finally, the 10-year differentials are converted to annual differentials by dividing by 10.

Application of the migration differentials involves multiplying the annual differentials by the number of years in the estimate period (quarter years are ignored) and then adding these period differentials to the period school-age migration rates. This results in single year of age migration rates, cumulated to the estimate date. These rates are applied to a migration base (cohort on the estimate date minus 1/2 deaths to cohort) to get the period single year of age net migration component for ages 17-64.

Sex distribution. The components (for ages 0 to 64) were not derived by sex, but sex detail is developed with the following steps: (1) The 1980 census proportion of male civilian population is calculated for each year of age (ages 0 to 64) by State; (2) national sex ratios by single year of age are calculated for both the 1980 census civilian population and for the 1981 to 1986 civilian estimates; (3) the change in the national sex

[14]The smoothing procedure used is the Whittaker-Henderson graduation technique. See Morton D. Miller, *Elements of Graduation*, Franklin Publishing Company, Philadelphia, PA, 1949.

ratios between the estimate year and the census base year are used to update the 1980 State ratios; and (4) these updated State ratios are applied to the State single-year civilian population estimates for both sexes to obtain civilian sex detail by age.

Armed Forces data. Armed Forces data are obtained from reports of the Departments of Defense and Transportation, on military personnel assigned by installation for each State. State Armed Forces data are not provided by age or sex, although national level data are.

All military persons are assumed to be between the ages of 17 and 64. National proportions are used to develop State Armed Forces cohort population estimates by age and sex. National proportions were also used to assign an age-sex distribution to the Armed Forces data for each State on the estimate date. Movement from the civilian to the military population for each State by age is estimated by taking the difference between: (1) the number of persons in the age group serving in the Armed Forces on the estimate date who reported the State as their preservice residence and (2) the number of persons in that age cohort serving in the Armed Forces on April 1, 1980, who reported that State as their preservice residence. An allowance is made for former residents of the State in the age cohort who died during the period while serving in the Armed Forces.

Population 65 and over. State estimates of the population 65 and over by single year of age and sex are based on the change in the number of persons covered under the Medicare program. Medicare enrollment by sex for 2-year and 5-year age groups (up to age 85 and over) is used for each July, from 1979 to 1985. The 1979 and 1980 data are interpolated to get enrollment figures for April 1, 1980, and the changes in the last 2 years of enrollment are used to estimate July 1, 1986, enrollment.

The 1980 State population proportions by age are used to distribute the Medicare enrollment to single years of age up to age 85 and over. The estimates for each single year of age and sex over age 65 result from adding to the 1980 census population the change in Medicare enrollment between April 1, 1980, and the estimate date. As a final step, each age sex-cell is prorated to an independent national estimate.

Accuracy of Age-Sex Estimates

As a routine part of the estimates program, the Bureau of the Census measures the accuracy of the estimates by comparing them to the latest decennial census counts. Based on these evaluations, refinements in methodology are often implemented in an effort to improve the accuracy of the estimates. The results of the Bureau's evaluation of the all-ages State population estimates for the 1970's decade, and the test of methodologies used to produce them, are outlined in Current Population Reports, Series P-25, Nos. 933 and 957. The results of the Bureau's 1980 test of the State age-sex estimates and the logic and limitations behind the methodology are discussed in the following paragraphs.

In Series P-25, No. 933, the problems of comparability between the 1970 and 1980 censuses were outlined. The lack of comparability was reflected in the large 1980 national error of closure of 4.7 million.[15] Among the probable contributors to this national error were (1) differences in the completeness of coverage in the census counts in 1970 and 1980, (2) omission of any adjustment in the estimates for undocumented aliens (some of whom were counted in the 1980 census), and (3) duplicate counting in the 1980 census.

Two approaches are used in evaluating the 1970-based State age estimates. The first approach is to simply compare the 1980 census counts and the 1980 State age estimates as computed. However, this yields biased results due to the 2.1 percent National error of closure. While there are estimates of 1970 undercount adjustments available for the all-ages State estimates, no such undercount adjustments were available for States by detailed age.

The second approach eliminates the bias by prorating the 1980 age estimates within a State to the State 1980 all-ages census count. This prorating also has the effect of eliminating the amount of deviation between the estimate and census count due to any inaccuracies in the independent national and all-age State estimates used as controls.

The procedure used to estimate State population by age in the 1970's yields estimates for 23 ages or age groups. For publication purposes, the estimates were summed to broad age groups that had relevance to life cycle stages. They were the pre-school (age under 5), school-age (5-17), young adult (18-24), adult (25-44), middle-age (45-64), and the elderly (65 and over) populations for States. Age detail by sex was not a part of the State age estimates program. Appendix table A-1 shows the percent deviation of the April 1, 1980, postcensal (1970-based) estimates from the April 1, 1980, census counts by broad age groups, with and without prorating to the 1980 census count. The average percent differences for the six prorated groups shown in table A-1 are as follows:[16]

Under 5	5-17	18-24	25-44	45-64	65+
3.5	1.5	3.1	2.8	3.2	1.2

Under-5 and 5-17 age groups. The population estimates of the under 5 age group had the largest average

[15]The error of closure (the difference between the census count and the estimate for the census date based on the previous census) was only 379,000 in 1970 and 3,000 in 1960.

[16]Unless stated otherwise, errors discussed in the remainder of this section are based on prorated estimates.

errors of all six age groups (3.5 percent). Without the District of Columbia's error of 31.4 percent, the average error would have been 3.0 percent. Births make up the largest part of the cohort in the under-5 age estimates, and are considered relatively accurate since they are based on certificates filed through the vital statistics offices of each State and the District of Columbia.[17] The modified procedure brought the average error in the estimates of the under-5 age group from 3.5 percent to 1.8 percent, and the number of errors over 5 percent from 10 to 2.

The estimates for the 5-17 age group displayed a low average error of 1.5 percent. Again the District of Columbia experienced the largest error with 15.2 percent. The next highest error was Alaska, (6.5 percent), followed by Nevada (5.3 percent). No other State was over 5 percent. The estimates for the 5-17 age group performed well because of their close correspondence to the population covered by school enrollment. The modified procedure was not tested for the 5-17 age group; however, it probably provides only a marginal improvement in the accuracy of the estimates for this age group. The Bureau did test estimates of the 5-to-14-year-olds, using the new procedure against the 1980 census, and they showed an average error of 1.5 percent compared to 1.8 percent from the old methodology.

18-24 and 25-44 age groups. The high mobility of persons in the 18 to 24 age group makes this one of the most difficult age groups to estimate. In this age group, the average error was 3.1 percent, with Alaska topping the list with an error of 23.0 percent, followed by West Virginia at -9.2 percent. Nine states had errors of over 5 percent. A 1970-based estimate using the modified procedure could not be generated for this age group or for the 25 to 44 age group due to the lack of comparable 1965-70 migration data.

The 25-44 age estimates experienced a moderate average error of 2.8 percent. Eight states had errors of over 5 percent with Alaska the largest at -15.7 percent. The migration for persons in this age group relates fairly closely to school-age migration, since these are parents of school children. Persons of this age group remain relatively settled, and do not have the high mobility of the 18-to-24-year-olds.

45-64 age group. This is a transition age group. Persons in this age group generally no longer have children in elementary school, and many are entering retirement, yet they are not eligible to enroll in Medicare.[18] The 1970-based estimates for this age group showed the second highest average error of 3.2 percent. Ten States were over 5 percent, with Wyoming the largest at 25.8 percent, followed by North Dakota at 9.5 percent. Here again, the 1965-70 migration detail was not available to test the modified procedure with a 1970-based estimate.

65-and-over age group. As expected, the 65 and over age estimates tested well, with the lowest average error of the six age groups (1.2 percent). Only 2 States had errors of over 5 percent, Alaska (-6.0 percent) and Nevada (5.4 percent), and 29 States had errors of under 1.0 percent.

As described in the methodology section, the modified procedure has expanded the age detail to single years of age (65 to 84) by sex, terminating at age 85 and over. However, only the age groups 65 to 74 and 75 and over are shown in this report. In the 1980 test of this expanded age detail, only 5-year Medicare enrollment data were available (instead of 2- and 5-year enrollment by sex) to make 1970-based estimates. The average errors of these estimates are: ages 65 to 69 (1.9 percent), age 70 to 74 (2.7 percent), ages 75 to 79 (7.8 percent), ages 80 to 84 (2.7 percent), and ages 85 and over (9.8 percent). Analysis of the 1970-based age estimates for these ages were clouded by problems with the inflation-deflation factors in the national age estimates which are used as controls.[19] An approximation of the average errors of the two Medicare-based age estimates (both sexes) published in this report are: ages 65 to 74 (2.2 percent), and ages 75 and over (2.4 percent). Even though the individual age estimates provided by Medicare enrollment may not be as accurate as estimates of the 65 and over as a whole, the average errors are still within an acceptable range.

Migration. The estimate of net migration is the most likely source of error in any population estimate. Data sources that indicate State migration by age are rare. Since school enrollment remains one of the few data items that can be collected from all 50 States (and the District of Columbia), with relative completeness and accuracy, it is used as the symptomatic indicator for net migration.

To develop the net migration component for ages under 17 years, the Census Bureau modified its 1970's methodology to make more accurate and flexible use of the amount of school-age migration. The assumption that each single year of age shares equally in the school-age migration should prove reasonable, given that there are no abrupt changes in State birth rates.

For the net migration of the 17-to-64-year-olds, the Bureau has retained the past procedure of relating school-age migration rates to other age-specific migra-

[17]In the District of Columbia, it is likely there is a problem of misreporting of place of birth for some Maryland and Virginia residents who give birth in D.C. hospitals.

[18]There are future plans to relate the migration for part of this age group (possibly ages 55 to 64) to residual migration based on Medicare enrollment.

[19]For an explanation of inflation-deflation, see Current Population Reports, Series P-25, No. 1000.

tion rates. The main assumption here is that the 1975-80 relationship between a State's school-age migration rate and any single-year-of-age migration rate will stay constant into the 1980's. The 1970's procedure has been somewhat refined, with a greater emphasis placed on developing accurate migration differentials. Improvements now incorporated include: (1) use of a more appropriate migration base—both-sexes civilian population is now used to calculate the 1975-80 in and outmigration rates instead of 15-44 female population; (2) use of a smoothing technique on the raw 5-year in and outmigration rates; and (3) creation of single-year-of-age migration differentials as opposed to differentials for 5- or 10-year age groups. Since a 1965-70 migration file comparable to the 1975-80 file was not available, the modified procedure for creating migration differentials could not be tested against the 1980 census.

Sex detail. Estimates of the 1980 population of States by both age and sex using the new procedure, could not be generated to test against the 1980 census. To offset this limitation, the Bureau did test the application of State specific sex ratios by applying an updated 1970 census sex ratio to the 1980 census both-sexes population to estimate 1980 male population by age (ages under 65). The average errors (no prorating was involved) for the broad age groups are:[20]

Under 5	5- 17	18-24	25-44	45- 64
0.3	0.3	2.9	1.7	1.2

The principal assumption involved in using updated sex ratios is that for each State, the 1980 ratio of males to both-sexes population (by single year of age) changes throughout the 1980's by the same amount the comparable national ratio changes. This assumption should prove fairly workable, given there are no sudden changes in the civilian sex structure of a State's population. Such a situation did occur in Alaska with the entry of the pipeline workers during the early 1970's.

Household Estimates

The method used to prepare the estimates of households by State is based on national trends and State trends in the adult population (18 years and over) per household and is hereafter referred to as the population-per-household method. [21]State household estimates published for the 1981-84 period in Current Population Reports, Series P-25, No. 974 were developed using only a national trends variant of the population-per-household method. Subsequent research suggested that for some States, a State trends variant of the method or a weighted average of national trends and State trends variants yields more accurate household estimates. State household estimates published for the 1981-85 period in Current Population Reports, Series P-25, No. 998 were based on the new methodology using the national trends and State trends variants of the population-per-household method. The 1981-85 household estimates in this report differ from those published in Series P-25, No. 998 because of revisions in the population estimates by age for States, as discussed earlier in this report.

The national trends and State trends variants of the population-per-household method both require estimates of the household population 18 years and over and of the population 18 years and over per household. Annual estimates of the population 18 years and over by State are not available separately for persons living in households or in group quarters. The total group quarters population for each State is estimated by adding the group quarters population covered by administrative data to an estimate of the remaining group quarters population. The latter estimate is derived by assuming that the ratio of the remaining group quarters population to the population 18 years and over excluding persons in group quarters covered by administrative data was the same as in 1980. The available annual data on group quarters population by State are limited to administrative data which included 56 percent of the group quarters population enumerated in the 1980 census and which include major group quarters facilities like college dormitories and military barracks. Since the administrative data are not available by age, and since 95 percent of the group quarters population in the 1980 census was 18 years and over, it is assumed for operational purposes that the entire group quarters population was 18 years and over. An evaluation of this assumption for the 1970-80 decade showed no effect on the reliability of household estimates for 1980. This is not surprising because the group quarters population under age 18 in 1980 (275,000) represented only 0.1 percent of the total population. The term "adult population" is defined here as the population 18 years and over minus the group quarters population (all ages) and is a close approximation of the household population 18 years and over.

The national trends variant of the population-per-household method assumes that since the most recent census, the proportionate change in the adult population per household in a State is the same as in the Nation as a whole:

$$\frac{r_{iy}}{r_{i(1980)}} = \frac{R_y}{R_{(1980)}} \text{ and } r_{iy} = \frac{R_y \cdot r_{i(1980)}}{R_{(1980)}}$$

[20]This test used resident instead of civilian population. With civilian population, lower errors would be expected in the groups involving military ages.

[21]Regarding methodological research on household estimation, see Prithwis Das Gupta, Campbell Gibson, Roger Herriot, Enrique Lamas, and Meyer Zitter, "New Approaches to Estimating Households and Their Characteristics for States and Counties," in Bureau of the Census, *Proceedings of the Second Annual Research Conference: March 23-26, 1986* (June 1986), pp. 83-110.

where

r_{iy} = the adult population per household for State i in year y;

r_i (1980) = the adult population per household for State i in 1980;

R_y = the adult population per household for the United States in year y (based on the adult population divided by a 12-month average of households from the Current Population Survey); and

$R_{(1980)}$ = the adult population per household for the United States in 1980.

The estimate of a State's adult population can then be used to estimate households:

$$h_{iy} = \frac{p_{iy}}{r_{iy}}$$

where h_{iy} = households for State i in year y; and
p_{iy} = adult population for State i in year y.

The State trends variant of the population-per-household method assumes that the average annual change in the adult population per household for a State in the 1970-80 period *relative to the national change* continues after 1980:

$$r_{iy} = r_{i(1980)} + (R_y - R_{(1980)}) + (d_{i(1970\text{-}1980)} - D_{(1970\text{-}1980)}) * \frac{t}{10}$$

where $d_{i(1970\text{-}1980)} = r_{i(1980)} - r_{i(1970)}$;
$D_{(1970\text{-}1980)} = R_{(1980)} - R_{(1970)}$; and

t = the number of years from April 1, 1980, to the estimate date.

The estimate of a State's adult population can then be used to estimate households as shown above for the national trends variant.

The national trends variant of the population-per-household method does not allow for proportionate convergence or divergence between the adult population per household in a State and the Nation. The State trends variant allows for convergence or divergence to be determined by trends of the preceding decade (1970-80). The weighting of the two variants is discussed in the section, "Accuracy of Household Estimates."

Since the population-per-household method requires the estimation of the group quarters population by State, these results can be used to estimate household population (resident population minus group quarters population) which then can be divided into estimated households to obtain estimates of average population per household for States. Estimates of average population per household are shown in table 9; however, it should be noted that these estimates, which show a decline from 2.75 on April 1, 1980, to 2.65 on July 1, 1986, for the United States, are not totally consistent with data from the March supplement to the Current Population Survey (CPS) which show a decline from 2.76 to 2.67 for the Nation, as discussed in the section on household trends. In addition to the fact that the two sets of estimates are for slightly different dates in 1980 and 1986, the data from the CPS are subject to sampling variability and include some college students (especially undergraduates living in group quarters such as dormitories) with their parents' households in contrast to the decennial census which enumerates college students at their usual place of residence while attending college.

Accuracy of Household Estimates

The accuracy of the State household estimates depends on the accuracy of the underlying data and of the population-per-household method. The sources of data are the 1970 and 1980 censuses of population, the Census Bureau's annual population estimates program, and the Current Population Survey. The major assumption concerning the underlying data is that postcensal estimates of the population 18 years and over by State are reliable.[22]

Both the national trends variant and the States trends variant of the population-per-household method were tested for the 1970-80 intercensal decade to determine the viability of their underlying assumptions. It should be stressed that this test excludes the effect of errors in the underlying age estimates. Census data on population in 1970 and 1980 and census data on households in 1970 were used to estimate households in 1980 with the national trends variant. For the State trends variant, 1960 census data on population and households were used also because the 1960-70 decade was used to establish base period trends.

The results of the evaluation are shown in table F. The median and mean (average) errors in the 1980 household estimates based on the national trends variant (0.7 percent and 0.8 percent) were lower than the corresponding errors based on the State trends variant (1.0 percent and 1.2 percent). The root mean square error based on the national trends variant (1.0 percent) was much less than the corresponding error based on the State trends variant (2.5 percent), due partly to two extreme errors produced by the State trends variant: -6.1 percent in Alaska and +4.4 percent in the District of Columbia.

While the national trends variant generally performed better than the State trends variant, the State trends variant yielded lower errors in 1980 households in 19 of

[22] In one comparison for 1980, the mean (average) error in State household estimates using post-1970 census population estimates was about 3 percent, compared with about 1 percent using 1980 census age data; however, given the large error of closure in the 1980 census, this comparison may overstate the additional error that would be expected due to errors in the underlying age estimates. Ibid., p. 85.

the 50 States and the District of Columbia, including the four States in which the national trends variant produced errors exceeding 1.5 percent: +2.9 percent in California, -2.2 percent in North Carolina, -1.9 percent in North Dakota, and -1.7 percent in Kentucky. With the notable exception of California, the State trends variant in general performed better in the more rural States, especially in States where the adult population per household fell more rapidly than in the nation as a whole in both the 1960-70 and 1970-80 decades.

In California, the State trends variant yielded a lower error than the national trends variant in the 1980 household estimate because the decline in the adult population per household (from 1.959 in 1960 to 1.938 in 1970 to 1.936 in 1980) was much less than the national decline (from 2.078 in 1960 to 2.013 in 1970 to 1.953 in 1980) in both decades. One factor contributing to the more moderate decline in California was the increased proportion of Hispanics and Asians in the State's population, because these population groups typically have above-average adult populations per household. While the definitions were not strictly comparable, Hispanics and Asians together increased from about 15 percent to about 25 percent of California's population between 1970 and 1980. In 1980, the adult population per household in California was about 2.3 for the Hispanic population and about 2.4 for the Asian population.[23] The household estimates in this report for California are based on the State trends variant of the population- per-household method and thus implicitly assume a continued rapid increase in the combined Hispanic and Asian proportion of the population.[24]

As suggested by the preceding discussion, a combination of 1980 State household estimates using the variant for each State that produced the lowest error (32 for national trends and 19 for State trends) significantly lowered the overall error (table F). The median and mean errors fell to 0.5 percent, the root mean square error fell to 0.6 percent, and in no State was the error as large as 1.5 percent.

In producing State household estimates for the 1981-86 period, the national trends variant was used in 20 states, the State trends variant was used in 11 States, and the two variants were weighted in 20 States. In the 31 States in which both variants underestimated or overestimated 1980 households, the variant yielding the lowest error was used to produce postcensal household estimates. In the 20 States in which one variant underestimated and one variant overestimated 1980 households, the variants were weighted between 0 and 1 to produce 1980 households, and these weights for each State were used to produce postcensal household estimates. For example, if the errors in 1980 household estimates for a State were +1.0 percent based on the national trends variant and -1.5 percent based on the State trends variant, the variants received weights of 0.6 and 0.4, respectively, in producing postcensal household estimates.

Annual estimates of households for States could be derived from the monthly Current Population Survey (CPS) using 12-month averages. This method has the advantage (subject to sampling variability) of providing symptomatic postcensal data on household trends for States. However, estimates based on the CPS were not used in developing the household estimates published in this report for two reasons. First, independent population controls for the CPS include estimates of the civilian noninstitutional population 16 years and over by State which are from the same source (the Census Bureau's annual estimates program) as estimates of the population 18 years and over by State. Thus CPS-based estimates of households by State are not independent (or even largely independent) of the estimates based on the population-per-household method. Second, the sampling variability of CPS-based estimates of households for States is relatively large. More specifically, the 95-percent confidence intervals for the CPS-based estimates of households for States are generally much larger than the errors that would be expected based on the population-per-household method in light of the results of the evaluation summarized in table F.

Table F. Percent Errors in 1980 Household Estimates for States

(Based on the population-per-household method)

Percent error[1]	National trends variant	State trends variant	Best variant for each State
Total[2]	51	51	51
0.0 up to 0.5	20	14	26
0.5 up to 1.0	17	11	19
1.0 up to 1.5	10	11	6
1.5 up to 2.0	2	6	-
2.0 up to 2.5	1	7	-
2.5 up to 3.0	1	-	-
3.0 and over	-	2	-
Median error (percent)	0.7	1.0	0.5
Mean error (percent)	0.8	1.2	0.5
Root mean square error (percent)[3]	1.0	2.5	0.6

- Represents zero.

[1] Without regard to sign.

[2] Including the District of Columbia.

[3] The root mean square error = $\sqrt{\sum_{i=1}^{51} e_i^2 / 51}$

where

e_i is the error of the estimate for State i.

[23] See 1970 Census of Population, Volume 1, Part 6., (1973), and 1980 Census of Population, Volume 1, Chapters B and D, Part 6, (1982 and 1983).

[24] See also the estimates published by the State of California (Population Research Unit, Department of Finance, 1025 P Street, Sacramento, CA 95814). These household estimates, which are based on a housing unit method and are for January 1 of each year, show the following (in thousands): 1981—8,772; 1982—8,914; 1983—9,009; 1984—9,131; 1985—9,310; 1986—9,530; 1987—9,774.

DEFINITIONS AND EXPLANATIONS

Household. A household consists of all the persons who occupy a housing unit. A house, an apartment or other group of rooms, or a single room, is regarded as a housing unit when it is occupied or intended for occupancy as separate living quarters; that is, when the occupants do not live and eat with any other persons in the structure and there is direct access from the outside or through a common hall.

A household includes the related family members and all the unrelated persons, if any, such as lodgers, foster children, wards, or employees who share the housing unit. A person living alone in a housing unit, or a group of unrelated persons sharing a housing unit as partners, is also counted as a household. If there are ten or more unrelated persons living together or nine or more who are unrelated to the person in charge, the living quarters are defined as group quarters and not as a housing unit.

Group quarters. All persons not living in households are classified as living in group quarters. There are two categories of persons in group quarters. The first category is inmates of institutions and includes persons under care or custody in institutions. Examples of institutions include facilities for the physically or mentally handicapped, homes for the elderly, orphanages, and correctional institutions. The second category is "other" and includes all persons in group quarters who are not inmates of institutions. Examples of other group quarters include college dormitories, military barracks, and rooming houses.

Householder. The householder is the person (or one of the persons) in whose name the housing unit is owned or rented (maintained) or, if there is no such person, any adult member, excluding roomers, boarders, or paid employees. If the house is owned or rented jointly by a married couple, the householder may be either the husband or the wife. The person designated as the householder is the "reference person" to whom the relationship of all other household members, if any, is recorded. The number of householders is equal to the number of households.

1980 CENSUS CORRECTIONS

Corrections to the tabulated 1980 census counts are not included in any of the tables or calculations shown in this report. However, corrected counts are used in the development of county and subcounty estimates published in Series P-26. To date, only four States have received corrections of one thousand or more, with Texas being the largest at -3,679 persons.

ROUNDING OF ESTIMATES

The population and household estimates in the tables have been rounded to the nearest thousand without being adjusted to group totals, which are independently rounded.

RELATED REPORTS

The estimates shown in this report are consistent with the estimates by age for the U.S. for 1981 to 1986 contained in Current Population Reports, Series P-25, No. 1000 and with estimates of households in Current Population Reports, Series P-20, No. 412. All estimates for the 1980's are consistent with 1980 census data contained in 1980 Census of Population, PC80-1-A, Number of Inhabitants, and PC80-1-B, General Population Characteristics.

[1] Estimated household population divided by estimated number of households. The household population is the resident population minus the group quarters population. See methodology concerning estimation of the group quarters population and concerning the difference between these estimates of average population per household and those discussed in the text.

[2] See methodology concerning household estimates for California.

Table A-1. Percent Error of State Population Estimates by Broad Age Groups: April 1, 1980, Using 1970's Procedure

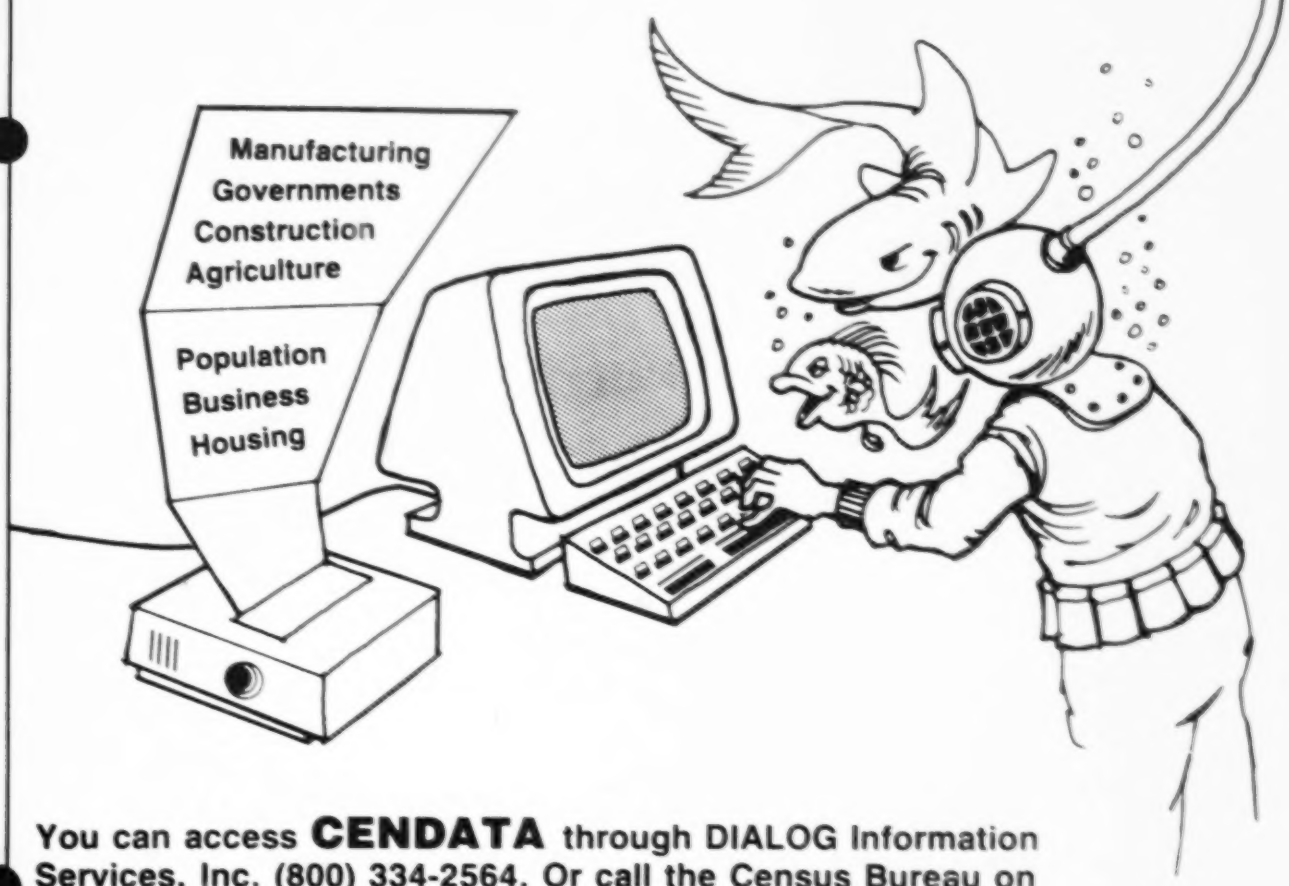
WHAT'S YOUR LINE?

It's ONLINE!

NOW whatever you do, wherever you go, we've got data for you. In more depth than ever—

CENDATA™—the Census Bureau's online system—instantly provides the facts you need for decisions in virtually every area. It covers everything from ingots to elections, from rental vacancies to retail sales, from median family income to milk cows in Minnesota.



You can access CENDATA through DIALOG Information Services, Inc. (800) 334-2564. Or call the Census Bureau on (301) 763-2074 for more information.

Now key statistics are just a phone call away.
